GridView Widget

GridView Widget

Make item clickable link

```
[
    'attribute'=>'naam',
    'label' => 'Studentnaam',
    'contentOptions' => ['style' => 'width:600px; white-space: normal;'],
    'format' => 'raw',
    'value' => function ($data) {
        return Html::a($data->naam, ['/examen/update?id='.$data->id],['title'=> 'Edit',]);
     },
],

// for related table values, use
'value' => 'student.locatie',
```

Title of column name

Change the model, example:

```
public function attributeLabels() {
return [
'id' => 'ID',
'naam' => 'examennaam',
'datum_van' => 'van',
'datum_tot' => 'tot',
'actief' => 'actief',
];
}
```

The database column '*datum_van*' will be showed as '*van*'.

View column conditionally

```
[
    'class' => 'yii\grid\ActionColumn',
    'contentOptions' => ['style' => 'width:400px; white-space: normal;'],
    'header'=>'Actions',
    'template' => '{view} {update} {delete}',
    'visibleButtons'=>[
        'view'=> function($model){
             return $model->status!=1;
         },
    ]
],
```

Add own controller (copy)

```
[
    'class' => 'yii\grid\ActionColumn',
    'template' => '{download} {view} {update} {delete}',
    'buttons' => [
        'download' => function ($url) {
            return Html::a(
                '<span class="glyphicon glyphicon-arrow-down"></span>',
                ['another-controller/anotner-action', 'id' => $model->id],   // mag ook alleen url als je geen parameter wilt meegeven, dan hoef je geen array te maken.
                [
                    'title' => 'Download',
                    'data-pjax' => '0',
                ]
            );
        },
    ],
],

// Alternatief, copy button, niet vergeten in template te te zetten
    'buttons'=>[
         'copy' => function ($url, $model, $key) {
             return Html::a('<span class="glyphicon glyphicon-copy"></span>', ['copy', 'id'=>$model->id],['title'=>'Copy']);
         },
    ],
```

Boolean (toggle icon)

Show boolean, if clicked, change status.

```
 [
   'attribute'=>'actief',
   'contentOptions' => ['style' => 'width:10px;'],
   'format' => 'raw',
       'value' => function ($data) {
          // $status = icon 'ok' or icon 'minus' depending on $data->ctief
             $status = $data->actief ? '<span class="glyphicon glyphicon-ok"></span>' : '<span class="glyphicon
glyphicon-minus"></span>';
             return Html::a($status, '/rolspeler/toggle-actief?id='.$data->id);
        }
 ],

// Controller
 public function actionToggleActief($id) {
        // function toggles boolean actief, in this example only one row can be active, so we execute two queries
        $sql="update examen set actief=1 where id = :id; update examen set actief=0 where id != :id;";
        $params = array(':id'=> $id);
        Yii::$app->db->createCommand($sql)->bindValues($params)->execute();
        return $this->redirect(['index']); // go back to view
    }
```

In this example only one row can be active. If you want a simple toggle use SQL statement:

```
update <table> set abss(active = active-1)
```

Drop down in grid select

https://stackoverflow.com/questions/29231013/how-can-i-use-a-simple-dropdown-list-in-the-search-box-of-gridviewwidget-yii2

```
[
    'attribute'=>'attribute name',
    'filter'=>array("ID1"=>"Name1","ID2"=>"Name2"),
],

// of
```

```
[
    'attribute'=>'attribute name',
    'filter'=>ArrayHelper::map(Model::find()->asArray()->all(), 'ID', 'Name'),
],

// of

[
    'attribute' => 'attribute_name',
    'value' => 'attribute_value',
    'filter' => Html::activeDropDownList(
      $searchModel,
      'attribute_name',
                ArrayHelper::map(ModelName::find()->asArray()->all(), 'ID', 'Name'),
                ['class'=>'form-control','prompt' => 'Select Category']
            ),
],
```

In dit voorbeeld wordt er data uit een andere table/model gehaald. De foreign key moet worden ge-update aan de hand van de rolspelers table.

```
<?php

// ************************
// * in controller        *
// ************************

// pass rolspeler

$rolspeler = Rolspeler::find()->where(['actief' => '1'])->all();
return $this->render('index', [
     'searchModel' => $searchModel,
     'dataProvider' => $dataProvider,
     'rolspeler' => $rolspeler,
]);

// fucntion for update (ajax) call from form

public function actionUpdateStatus($id, $status, $rolspelerid) {
    $model = $this->findModel($id);
```

```
    $model->status=$status;
    $model->rolspelerid=$rolspelerid;
    $model->save();
}

// ************************
// * in view (index)      *
// ************************

// ajax call to update record

<script>
    function changeStatus(id, status, rolspelerid) {
        // console.log(val, id);
        $.ajax({
        url: "<?= Url::to(['update-status']) ?>",
            data: {id: id, 'status': status, 'rolspelerid': rolspelerid },
            cache: false
        }).done(function (html) {
            location.reload();
        });
    }
</script>

// prepare ass. array for the drop down.

<?php $rolspelerList = ArrayHelper::map($rolspeler,'id','naam'); ?>

...

<?= GridView::widget([
     'dataProvider' => $dataProvider,
     'filterModel' => $searchModel,
     'columns' => [

      // show dropdown and call ajax script that calls the methos/function in teh controller

     'format' => 'raw',
         'value' => function ($model) {
```

```
            return Html::dropDownList('status', $model->status, ['0'=>'Wachten','1'=>'Loopt','2'=>'Klaar'],
            ['onchange' => "changeStatus('$model->id', $(this).val(), '$model->rolspelerid')"]);
           }],

...
```

Column customization

In Yii2's GridView, each column in the grid can be customized using a variety of properties. These properties allow you to define how each column behaves, how it's rendered, and how it interacts with the data provided. Here's a list of common properties that you can specify in a column in Yii2 GridView:

attribute: The attribute name of the data model. The value of the attribute will be displayed in this column.
label: The label of the column in the header.
value: A PHP callable that returns the content of the column. It should be used if the column content is not directly tied to a model attribute.
format: How the data of this column will be formatted. Common formats include 'text', 'html', 'date', 'number', etc.
header: The header cell content. This will override the automatically generated header cell content.
footer: The footer cell content. This will override the automatically generated footer cell content.
headerOptions: HTML attributes for the header cell tag.
contentOptions: HTML attributes for the data cell tag.
footerOptions: HTML attributes for the footer cell tag.
visible: Whether the column is visible. If set to false, the column will not be displayed.
filter: The filter input content. This can be a string or an array to specify the type of filter input.
filterOptions: HTML attributes for the filter cell tag.
headerHtmlOptions: Deprecated, use `headerOptions` instead.
footerHtmlOptions: Deprecated, use `footerOptions` instead.
class: The class name of the column. Yii2 provides several built-in column types like `yii\grid\SerialColumn`, `yii\grid\DataColumn`, `yii\grid\CheckboxColumn`, etc.
enableSorting: Whether sorting is enabled for this column.
sortLinkOptions: HTML attributes for the sorting link.
filterInputOptions: HTML attributes for the filter input.
filterWidgetOptions: Configuration options for the filter widget.
noWrap: Whether to disable text wrapping for this column.
